

5. Change Considerations

5.1 Possible interventions considered

The recommended interventions should be understood as a connected set of controls, process improvements, and automation opportunities rather than isolated fixes. Together, they address the main failure points identified in the analysis and create the conditions for more reliable, transparent, and accountable onboarding.

Controls	
1) Documentation validation gate enforced by the system	Have a mandatory validation gate in the customer onboarding process so that incomplete applications are not progressed.
2) System prevents order creation	Orders cannot be processed until customer onboarding is complete and their account is active
3) Contractual obligation of transport subcontractors	Consider amending service agreements with transporters so that even subcontractors appointed by the primary transporters, are held financially liable should they not find customer-stamped PODs
1) End-to-end process owner	The appointment of a formal end-to-end process owner is introduced as a governance control to consistent accountability across departments, support escalation, and maintain process improvement over time.
Process Improvement	
2) Defined onboarding service levels	Set clear timelines for each stage of the onboarding process to ensure all relevant teams are informed
3) SOPs and work instructions	Develop standards of procedure and work instructions to all departments involved in onboarding, credit, compliance, transport, and POD handling, since no shared SOPs currently exist.
4) ScanCo adoption governance and enforcement	Make the ScanCo as the single mandatory repository for proof of parts and machine deliveries as well as the proof of service fulfilment.
5) Delegation framework for approvals	Define backup approvers and escalation routes for credit, screening, and activation decisions so that work can continue when key decision-makers are unavailable. Temporary reassignment should be formally recorded to ensure accountability and an audit trail

6) Consolidated customer onboarding master data form	Introduce a single structured onboarding form that captures all required customer information currently collected across multiple documents (cash/credit application, business party screening datasheet, and end-user certificate). The form should capture standardised data fields once, have all required compliance-related inputs, and provide structured sections aligned to each document requirement. Where necessary, system-generated outputs can be produced from the master data form to enable documentation.
Process Redesign	
1) Customer onboarding portal	Design a single customer-facing onboarding portal in ServiceNow that supports mandatory field validation, progress visibility, workflow routing, and integration of cross-departmental functions.
2) Restructured OTC model	Formalise handover points and responsibilities between Customer Care, Trade Compliance, Credit Control, MDM, and other relevant functions. This would reduce ambiguity, improve coordination, and create a more coherent end-to-end workflow.
Automation Opportunities	
1) Automated screening status notifications	Configure the workflow so that customers and internal users receive automatic updates when screening is completed, delayed, or returned for further action. This would reduce manual follow-up and improve process visibility.
2) Automated AR ageing alerts	Create alerts for overdue accounts at set thresholds to enable earlier intervention by finance staff. This will strengthen collections discipline and help reduce doubtful debt exposure.
3) Parallel approval workflows	Set up approvals to enable the execution of independent tasks in parallel, rather than sequentially. This method will reduce unnecessary delays between departments and shorten cycle times.
4) AI-supported document matching	Automate the matching of invoices in Cloud-based ERP system with supporting documents such as delivery notes, service reports, and timesheets stored in ScanCo.

	When invoices are created, key reference data is extracted and compared with corresponding fields from documents processed using Microsoft Azure AI Document Intelligence. Matching records are confirmed automatically, while missing or inconsistent documents trigger exception alerts routed via ServiceNow for resolution. This replaces manual reconciliation, reduces cross-system searches, improves accuracy, and provides real-time visibility of missing documentation, supporting faster dispute resolution and stronger Order-to-Cash control.

5.2 Recommended intervention

The recommended intervention is the implementation of a unified ServiceNow-based onboarding portal supported by standard operating procedures, work instructions, and formal process ownership. This solution directly addresses incomplete submissions, unclear responsibilities, repeated follow-ups, and the absence of a defined turnaround standard. It is the most coherent option because it combines workflow control, visibility, accountability, and standardisation in a single intervention rather than treating these issues separately. The appointment of an end-to-end process owner should be treated as a governance control supporting the portal rather than as a standalone operational fix. The process owner is responsible for maintaining the rules, enforcing escalation, monitoring performance, and ensuring that the redesigned process remains stable after implementation. In this sense, the technology and the governance structure are mutually reinforcing.
